Introduction to the Linux OS

Peter Huszár

KFA: Department of Atmospheric Physics

Pavel Řezníček

ÚČJF: Institute of particle and nuclear physics

November 12, 2025

Overview and Organization

Introduction to the Operation system Linux, focus on the command line, scripting, basic services and tools used in (not only) physics: tasks automation in data processing and modeling

Organization

• Graded Assessment (KZ): attendance to the lectures, worked out homeworks

Literature

Study materials and homeworks

http://kfa.mff.cuni.cz/linux

Syllabus

- UNIX systems, history, installation, basic applications
- ② Structure of the Linux OS, file systems, hierarchy of the file system
- Ommand line, shells, remote access (ssh, ftp)
- Processes and their administration, basic system commands, packages, printing
- Users, file and directory permissions
- Work with files and directories, file compression, links, partition
- Text-file processing commands, redirection, pipeline
- Regular expressions
- Ommand line based text editors
- User and system variables, output processing
- Scripts: basic construction, conditionals, loops, functions, automation
- Networking, server-client services: http, (s)ftp, scp, ssh, sshfs, nfs
- $oxed{3}$ Programming in Linux (examples of Fortran, C/C++, Python), version control systems, documents in Latex

Disk/partition/filesystem handling utilities

Huszár, Řezníček Linux: Introduction NOFY077 November 12, 2025 4 / 13

Files/directories are structures physically or virtually written into harddrives/flashdrives, cdrom/dvdroms, tapes, virtual memory etc. These are usually divided into partitions which enables to separate logically distinct parts of the filesystem hierarchy structure. For example /home will be placed on different partition than /.

- Each parition has its own filesystem (FS)
- Partitions are 'mounted' to directories
- df report file system disk space usage. It shows which partition is 'mounted' to which directory.
 - /dev/sda, /dev/sdb, /dev/sdc are 'device' files corresponding to individual devices
 - /dev/sda1, sda2 mean the partition number on the disk (i.e. each partition has a separate device file in /dev)
 - tmpfs is a temporal filesystem created in the RAM, so it behaves as a normal hraddisk, but when the computer is turned off, it is gone.
 - df -Th shows the type of the filesystems mounted (ext2, ext3, ext4, reiserfs, vfat, ntfs etc).
- Isblk very useful utility to show the disk/partitions structure/filesystems and IDs of partitions
- hdparm get/set SATA/IDE device parameters. Tool to use when it comes to tuning your hard disk or DVD drive, but it can also measure read speed, deliver valuable information about the device, change important drive settings, and even erase SSDs securely.

lsblk -f # get complete information about the disks/partitions/filesystems and disk UUIDs (see /etc/fstab) hdparm -I /dev/sda # For all kind of information about the SATA/IDE disk

5 / 13

Huszár, Řezníček Linux: Introduction NOFY077 November 12, 2025

fdisk (partitioning) and filesystem creation

 FDISK - manipulate disk partition table. A very powerful utility to create, modify and delete partitions on a disk. USE WITH CAUTION AS YOU CAN EASILY DAMAGE YOUR EXISTING FILES/DIRECTORIES!!! More info on: https://www.tldp.org/HOWTO/Partition/fdisk_partitioning.html or man fdisk.

```
fdisk -1 # shows all disks connected to the computer (needs root privileges) fdisk /dev/sdb # prompt to manipulate with disk /dev/sdb, press m to get all the commands
```

 Once partitions are created on a disk, we can create different filesystems (Linux File System list https:

```
//static.javatpoint.com/linux/images/linux-file-system2.png,
https://en.wikipedia.org/wiki/List_of_file_systems mkfs.filesystem
```

```
{\tt mkfs.ext4~/dev/sdb1~\#~create~Ext4~filesystem~on~disk~/dev/sdb~and~partition~1.}
```

• fsck - check and repair a Linux filesystem

```
{\tt fsck.ext4 / dev/sdb1 \# check \ and \ repairs \ the \ ext4 \ filesystem \ on \ disk / dev/sdb \ and \ partition \ 1.}
```

MEETIN

Mounting filesystems

In order to access the files/directories on the partitions, this partition has to be 'mounted'.

mount - mount a filesystem

```
mount -t type device dir # The standard form of the mount command # type is the filesystem type, device is the device file in /dev and dir is the directory where to mount mount /dev/sdb1 /data # -t type may be omitted as the system will find it out automatically mount -o ro /dev/sdb1 /data # "-o" = adding mount options, ro = read-only
```

mounting ISO filesystem (CD/DVD *.iso image)

```
mount /path/to/image.iso /media/iso -o loop
```

Mounting NFS - network filesystem

```
mount -t nfs 10.76.120.40:/volume1/d01 /home/nas01
```

• tmpfs - temporal/virtual filesystem represented in the RAM

```
mount -F tmpfs -o size=1G swap /mount/tmp # this takes 1G from the RAM and allocate it to /mnt/tmp
```

unmounting filesystems

```
umount /mount/point
```

7 / 13

MFF U

The /etc/fstab file

The /etc/fstab file is a system configuration file that contains all available disks, disk partitions, virtual disks and their options. Each file system is described on a separate line. Each line contains six fields separated by one or more spaces or tabs.

The mount command reads each line at system boot and mounts the disks according to the options given on the lines.

```
# <file system> <mount point> <type> <options> <dump> <pass>
# filesystem root disk
UUID=f3b12014-faea-49c8-9e9a-f397b002454d / ext4 errors=remount-ro 0 1
# boot partitions
UUID=515B-6053
                   /boot/efi vfat umask=0077 0 1
UUID=141ad68b-b7f4-4074-a89d-43801222d5fb none
                                                    swap sw
# 2T data disk
UUID=6f3ffadf-418f-4e15-baaf-93ca06ffaf54 /data ext4 errors=remount-ro 0
# NAS1 and NAS2
10.76.120.40:/volume1/d01
                           /home/nas01 nfs defaults 0 0
10.76.120.40:/volume2/d02
                           /home/nas02 nfs rw
# cesnet high capacity storage center Jihlava
sshfs#huszarpet@ssh.du4.cesnet.cz:/tape_tape/archive/VO_cuni_mff_meteo/home/huszarpet \
            /mnt/cesnet fuse defaults,idmap=user,IdentityFile=/home/huszi/.ssh/id_rsa,allow_other 0 0
```

- Disks can be specified either by the device file e.g. /dev/sda2, however, this is not uniq and can change if disk are connected to the computer in a different order.
- A much safer option is to specify the disks by their UUID number (lsblk -f /dev/sda2)
- Further options: type = FS type; options = mount options (like ro for read only); dump = backup operation with 'dump' (0/1); pass = FS check with fsck (root always 1, other 2, nocheck = 0)
- to mount the "lines" of fstab (when changes made) use mount -a.

8 / 13

Excercise - disk/partition handling utilities

A simple but frequent example

Suppose we got an old (or new) disk and want to format it as a single partition to the ext4 filesystem, then mount it to /mnt/mydisk.

- fdisk to repartition (delete old partitions)
- mkfs.ext4 to create a FS
- mount it (for one time use) and permanently via fstab

9 / 13

Text manipulation

Huszár, Řezníček Linux: Introduction NOFY077 November 12, 2025 10 / 13

Basic text manipulation commands

Commands to view and transform text(files); and to extract information about the text

cat, more and less - to view text file contents (read-only!)

```
cat /my/text/file.txt # writes the contents of the file

# on the terminal - the standard output (stdout) and returns to prompt

# seemingly useless command in case of long files, but wait-for-it;-)

# (e.g. for putting two file ater "each other" cat files! file2 > file_final)

more /my/text/file.txt # view text by pages ("Space"), q or ctrl-c to quit

less /my/text/file.txt # view text by pages, PageUp/PageDown,Up/Down keys, Space -- 'q' to quit

# less is more than more and unlike more, reads only that part of the file

# which is shown
```

 head and tail - we are oftne interested in what the begining/ending of text file contains

```
head -n 20 /my/text/file.txt # prints the first 20 lines of the textfile
head -n -20 my/text/file.txt # prints all but the last 20 lines
tail -n 20 /my/text/file.txt # prints the last 20 lines of the textfile
tail -n +20 /my/text/file.txt # prints the last lines starting with line number 20
# if -c is used instead -n in both cases
# printing applies for bytes (first N/last N bytes)
```

wc - word count (counts bytes/characters/words/lines)

ČJF FF UK

MFF UK

Basic text manipulation commands (cont'd)

Commands to view and transform text(files)

 cut - cuts parts of each line of a text ("vertical" version of head/tail). It uses "deliminator", default is the tabulator. Very useful to extract columns in a text file, where columns are separated by a certain character (e.g. comma)

```
cut -d"{deliminator}" -f1 /my/text/file.txt # for each line prints everything before the first appearance
# of the {deliminato} when it is the tabulator, -d is not import
cut -d":" -f1,3,5,10-15 # takes the first column, the 3rd, the 5th and than the 10-15.
# --complement, select the rest
# -d".", -d";", -d" ", -d"-", -d"a" etc.
cut -c X-Y # cut from Xth to the Yth character on each line of the input file
```

• paste - line-by-line merge files "next" to each other. This requires a delimiter, tabulator is again the default one

• fmt - simple text formatter

```
fmt /my/file.txt # by default puts all words in a single line and prints
fmt -w 10 /my/file.txt # print the text in the specified width (does not wrap words!!!)
fmt -t file.txt # add indentation for the first line different from others
fmt -u file.txt # uses one space between words and two spaces after sentences for formatting
```

KFA

12 / 13

MFF UK

Basic text manipulation commands (cont'd 2)

• sort - sort lines of file according to dictionary, numerical value etc.

```
sort -d /my/files.txt # dictionary sort
sort -b /my/files.txt # ignore leading blank characters
sort -n /my/file-with-numbers.txt # numeric sort
sort -r /my/file.txt # reverse the result
sort -u /my/file.txt # print only unique lines
sort -k 2 /my/file.txt # sort according to the second "column"
```

uniq - report/omit repeated lines (related to sort -u)

```
uniq -c /my/file.txt # prefix lines by the number of occurrences uniq -d/-u /my/file.txt # prints only duplicated lines/unique lines
```

• rev - a trivial utility that reverses each line characterwise

```
rev /my/file.txt # the output will be the file with same size but all lines in # reversed order (you can doubt the usefullness :-))
```

 join - join lines of two files on a common field (joins two "column" files with different columns as fields delimited by a delimiter based on values in selected columns)

```
join -t, -1 FILE1COLUMN -2 FILE2COLUMN FILE1 FILE2 # joins lines from both file based on # the value of FILE1COLUMN equals FILE2COLUMN join -t, -1 1 -2 2 file1 file2 # join lines of file1 with file2 where the value of columns 1 from # 1st file and column 2 from 2nd file equal; -t is the delimiter (e.g. -t,)
```

For join to be successfull, files must be sorted, unless –nocheck-order is used

-headers will skip the first line on each file as header line
